Key words: Nasopharynx; Pleomorphic adenoma; Minor salivary glands
Pleomorphic adenoma of the nasopharynx: a rare case with therapeutic misadventure

Abstract

**Background:** The benign tumours of nasopharynx are least encountered tumours in otolaryngology, as nasopharynx is considered one of notorious anatomical site for the malignant tumours. We present a rare pleomorphic adenoma of nasopharynx which was misdiagnosed.

**Case presentation:** An adult male presented with left nostril obstruction for five months. The examination found big mass extending from nasopharynx to oropharynx. The FNAC found it a carcinoma but it did not responded to radiotherapy. The excision biopsy of tumour revealed it as pleomorphic adenoma. We found only five published reports on this tumour arising from nasopharynx.

**Discussion and conclusion:** The pleomorphic adenoma of nasopharynx is rare. It can be misdiagnosed as malignant epithelial tumour on histopathology. The differentiation from its malignant variant is also difficult. A possibility of benign tumour should always be kept in nasopharyngeal growth with no evidence of metastasis. Pathologist should always examine the slides thoroughly before making a diagnosis and no provisional diagnosis should be made in scanty, poor cytology.
**Background:** Benign tumors of nasopharynx are rare since nasopharynx is a common site for malignant tumors. Pleomorphic adenoma is the most common benign tumor of the major and minor salivary glands, but rarely found in the nasopharynx. In this case report, we present a case of a large pleomorphic adenoma arising in the nasopharynx and extending to oropharynx that was diagnosed and managed as squamous cell carcinoma.

**Case presentation:** In Sep 2007, a 35-year-old male presented with a progressive nasal obstruction associated with left aural fullness, hearing loss and hyponasal speech for the past five months. Later, the patient saw a mass pushing the soft palate downwards and began having difficulty in swallowing solid food. Past history included a pyelolithotomy and gastrojujenostomy for duodenal ulcer.

A fine needle aspiration biopsy (FNAB) of the mass was done intra-orally and microscopic examination revealed a poor smear with scanty cells. The pathologist suggested the possibility of a squamous cell carcinoma and advised a direct biopsy for definitive diagnosis. On 19th Sep 2007, computed tomographic (CT) scan of the neck revealed a large mass of heterogeneous density involving the fossa of Rosenmuller, and extending to the vallecula through parapharyngeal space. The mass had heterogeneous contrast enhancement with central necrosis (Fig 1). Based on these features, radiologist suggested a malignant tumor of the nasopharynx.

A radiation oncologist evaluated the patient and investigations, and began radical chemo-radiation. However, the tumor did not regress despite receiving 20 Gray of radiation, and this led to a suspicion of a benign growth. On 25th March 2008, a fresh CT scan (Fig 2) was done and it showed nasopharyngeal tumor with same features as pre radiotherapy but increased in size as compared to earlier CT scan. Since there was no
histopathological evidence of the carcinoma, the intra-oral incisional biopsy was done and was found to be suggestive of a pleomorphic adenoma. A surgical intervention was planned, and tumor was excised by transpalatal approach under general anesthesia. Histological examination of the excised tumor confirmed a pleomorphic adenoma with no evidence of malignancy (Fig 3). The patient recovered well without any complication and had no recurrence in follow up of 1 year.

Discussion: The Fossa of Rosenmuller is a common site of squamous cell carcinoma of the nasopharynx. Nasal obstruction, epistaxis and adenopathy are common symptoms of nasopharyngeal carcinoma; however, the exact diagnosis of nasopharyngeal growth can be made only by an accurate histopathology.

Palate, nasal cavity and nasopharynx have abundant minor salivary glands and pleomorphic adenoma is the most common benign tumor of these glands. Pleomorphic adenoma arising in the nasal cavity has scanty or absent cartilaginous component which can make histological diagnosis difficult [1]. Compagno and Wong [2] reported that microscopically pleomorphic adenoma of the nasal cavity resembles mixed tumor of the major salivary glands but due to high epithelial cellularity and little stromal component these benign tumor can be mistaken for malignant epithelial neoplasm. Lam et al. [3] found skeletal muscle differentiation in pleomorphic adenoma of the nasopharynx which can simulate rhabdomyosarcoma.

Malignant tumors comprise about 40–50% in all the minor salivary gland tumors (7% are carcinoma ex pleomorphic adenoma) [4-7]. Pleomorphic adenoma has three malignant varieties: carcinoma ex pleomorphic adenoma, carcino-sarcoma and metastasizing pleomorphic adenoma. Carcinoma ex pleomorphic adenoma is a rare
mixed tumor developing from the epithelial component of the pleomorphic adenoma [7-9].

The malignant transformation in the pleomorphic adenoma has been linked to recurrence and multiple excisions [10,11], laminin, and collagen IV deposition [12,13]. Recently [14], it has been found that loss of β-catenin adhesion molecule is one of the factors responsible for development of pleomorphic adenoma and cytoplasmic accumulation of this molecule causes malignant transformation in pleomorphic adenoma.

CT scan does not provide significant differentiation between carcinoma ex pleomorphic adenoma (CXPA) and benign pleomorphic adenoma as CXPA can have malignant appearance or benign features similar to pleomorphic adenoma. On MRI, low T1 and T2-weighted signal intensity has been suggested as an indicator for carcinoma ex pleomorphic adenoma [15].

An extensive literature review revealed only five cases of pleomorphic adenoma arising in the nasopharynx [3,16-19]. Roh et al. [18] excised a pleomorphic adenoma of nasopharynx in a 61-year-old female by endoscope. They advocated use of endoscope in these cases to avoid injury to Eustachian tube. Lee et al. [19] reported a similar case in a elderly patient who had otalgia, aural fullness and tinnitus. The tumor was excised endoscopically and patient had no recurrence.

Although, radiotherapy is indicated in recurrent pleomorphic adenoma but in our case, diagnosis of carcinoma was made on cytology alone. The patient received chemoradiation but tumor increased in size, and then tumor was found to be a benign pleomorphic adenoma. In retrospective review of the case, we agreed that a major mistake occurred by not performing a direct tumor biopsy before starting chemo-
radiation. Possibly, myoepithelial or epithelial atypia with keratin debris in pleomorphic adenoma (Fig 4) led to cytological diagnosis of carcinoma. To make the issue more complex, there could be a possibility that the adenoma was undergoing malignant transformation and these changes were picked up in the cytology. After radiotherapy, malignant part disappeared and consequently we did not find any evidence of malignancy in the excised pleomorphic adenoma.

Conclusion: The pleomorphic adenoma was undergoing malignant changes or it was a misdiagnosis, we could not ascertain the exact pathology, as we had no pre-radiotherapy histopathological evidence. Who was at fault: clinician by not performing the biopsy, pathologist by not identifying the microscopic findings, radiologist who agreed to the provisional diagnosis or oncologist who started chemo-radiation without any histopathological proof? We cannot blame anyone rather than ourselves as the clinician are the most accountable.

In this case report, many questions remained unanswered but a lesson learnt was:

1. The possibility of benign tumor should be kept in the differential diagnosis of nasopharyngeal tumor without adenopathy.

2. The Pathologist should always examine the slides thoroughly before making a diagnosis and especially of carcinoma. Diagnosis should not be made in scanty and poor cytology.

3. An adequate tissue specimen should be obtained especially for cytological diagnosis as pleomorphic adenoma can simulate as a carcinoma.
4. No patient should be taken for chemo-radiation without any histopathological evidence.

Consent: Written informed consent was obtained from the patient for publication of this case report and any accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal.

List of abbreviations used: **FNAB**: Fine needle aspiration biopsy; **CT**: Computed tomography; **MRI**: Magnetic resonance image; **CXPA**: Carcinoma ex pleomorphic adenoma; **H & E**: Hemotoxylin and eosin
